High Performance Programming, Lecture 5

Optimization II: memory usage and some other things

HPP 1 / 47

Follow up on lab 2: Time measurement

```
time ./regularcode
              real
                       0m1.869s
                       0m1.868s
              user
               sys
                       0m0.000s
time ./sleepycode
              real
                       0m7.044s
                       0m2.040s
              user
                       0m0.000s
               sys
time ./mallocycode
              real
                       0m2.387s
                       0m2.176s
              user
                       0m0.208s
               sys
time ./threadedcode
                       0m1.933s
              real
                       0m3.860s
              user
                       0m0.000s
               sys
```

gdb debugger: stack frame, local addresses

Stack frame is the collection of all data on the stack associated with a function call

Corresponding registers:

Stack pointer (%rsp) stores the address of the top of stack

Frame pointer (%rbp) stores the address of the stack pointer when a function begins executing

https://godbolt.org/z/-YxQq5

HPP 3 / 47

gdb debugger: stack frame, local addresses

```
Breakpoint 2, gg (a=0) at littlecode.c:7
7 int p = 55;
(gdb) info locals
                                          # at the start
 of gg
p = 0
q = 0
r = 0
c = 0 , 000
(gdb) c
Continuing.
Breakpoint 4, gg (a=0) at littlecode.c:17
17 return r;
(gdb) info locals
                                          # at the end
 of gg
p = 55
q = 66
r = 621
c = 100 'd'
                                 HPP
                                                         4 / 47
```

gdb debugger: stack frame, local addresses

```
Breakpoint 1, hh (a=0) at littlecode.c:22
22    int s = 1;
(gdb) info locals
i = 55  # garbage value (leftovers from the gg call)
s = 66  # garbage value (leftovers from the gg call)
(gdb)
```

HPP 5/47

gdb debugger: ascii characters

```
(gdb) p c

$7 = 43 '+

# or

(gdb) p c

$14 = 16 '\020
```

From the gdb manual:

Regard as an integer and print it as a character constant. This prints both the numerical value and its character representation. The character representation is replaced with the octal escape '\nnn' for characters outside the 7-bit ASCII range.

See ASCII table: http://www.asciitable.com/

HPP 6 / 47

More gdb debugger options

(gdb) continue (or just type letter c)

means proceed to the next breakpoint (or untill the end of the program if there are no breakpoints)

(gdb) next

execute just the next line of code treat function calls as one instruction, do not step inside

(gdb) step

execute just the next line of code step inside each function call

(gdb) finish

run until the current function is finished

(gdb) break myfunc

set a breakpoint

after running the program, the execution will stop in this function

(gdb) delete myfunc delete a specified breakpoint

Comment: typing "step" or "next" a lot of times can be tedious. If you just press ENTER, gdb will repeat the same command you just gave it.

HPP 7 / 47

Memory is one-dimensional

Any 2D, 3D, etc. array must somehow be mapped to 1D memory address space.

Example: matrix A (2D array $N \times N$), matrix element A_{ij} can be accessed as A[i * N + j] (or as A[j * N + i] depending on convention used).

HPP 8 / 47

$Optimization\ overview$

Program performance can be improved by:

- I: Doing less work
- II: Waiting less for data ← this lecture!
- III: Doing the work faster
- IV: Using less space (to fit a bigger problem)

HPP 9 / 47

Outline

Things covered in this lecture:

- Memory usage
- Cache, data locality, blocking techniques
- Function side effects, pure functions
- The "const" keyword
- The "restrict" keyword

 $\mathrm{HPP} \qquad \qquad 10 \; / \; 47$

Reading

Reading for this module:

```
• Fog 7.1 : "Different kinds of variable storage"
```

• Fog 8.3 : "Obstacles to optimization by compiler"

• Fog 9 : "Optimizing memory access"

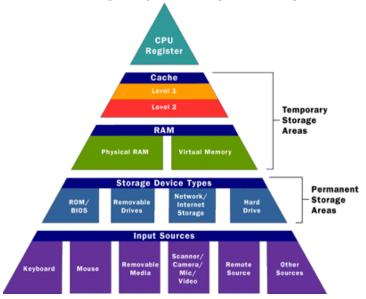

• Pacheco 2.2.1: "The basics of caching"

Pacheco 2.2.2: "Cache mappings"

• Pacheco 2.2.3: "Caches and programs: an example"

HPP 11 / 47

Example of memory hierarhy

HPP 12 / 47

C language works with memory addresses

 The C language syntax lets us work with pointers to memory addresses.

- However, a C program does typically not explicitly decide what is stored in cache and in registers.
 - register keyword hints the compiler to use very fast memory if possible. i.e. register int a;
 - Usually doesn't make much difference. Compilers don't care any more.

HPP 13 / 47

Memory allocation Optimizations

Avoid too many small allocations

 \longrightarrow Avoid having many malloc/free calls for small memory buffers.

Ways to do this:

- Allocate few larger blocks and get smaller blocks by pointing into large blocks
- Use a pre-allocated work buffer instead of doing malloc/free each time a function is called
- Put small things on stack instead of calling malloc/free

HPP 14 / 47

Cache and data locality

Programs often re-use nearby memory locations (locality principle):

- Temporal locality: the same address is likely to be needed again soon
- Spatial locality: nearby addresses likely to be needed soon

Cache is a collection of memory locations that can be accessed in less time than some other memory locations.

This is why **CPU caches** are built into the hardware.

HPP 15 / 47

Hardware is complex Example of info from AMD opt. manuel

In the "Software Optimization Guide for AMD Family 17h Processors" we can for example find info like this:

Pages 23-25: detailed info about L1, L2, L3 caches.

The AMD Family 17h processor uses five caches at three hierarchy levels to accelerate instruction execution and data processing:

- · Dedicated L1 instruction cache
- Dedicated L1 data cache
- · Dedicated L1 op cache
- Unified (instruction and data) L2 cache per core
- 4-Mbyte or 8-Mbyte L3 cache (depending on configuration)

HPP 16 / 47

Caches

Several levels of cache with varying latency

- L1 (approx. 10-100 kB) 1-5 cycles
- L2 (256 kB-) 10-20 cycles
- L3 (> 2 MB), slower

Caches organized into units called "cache lines", often 64 or 128 bytes each: a whole cache line is fetched from memory.

L1 cache of two types: L1d (data) and L1i (instruction) cache.

HPP 17 / 47

Example

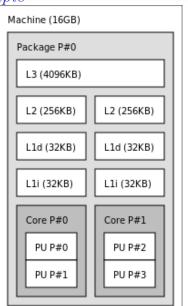

Intel Core i7-4600U CPU @ 2.10GHz

cat /proc/cpuinfo

lscpu

To get this picture run:

lstopo --output-format
 png -v --no-io > cpu
 .png

HPP 19 / 47

Example of costs for cache/memory access

Cycles		
<u>≤ 1</u>		
3		
14		
240		

(Numbers listed by Intel for a Pentium M)

 $\mathrm{HPP} \qquad \qquad 20 \; / \; 47$

How caches work - cache lines

- Cache divided into cache lines
- When memory is read into cache, a whole cache line is always read at the same time
- Good if we have data locality: nearby memory accesses will be fast
- Typical cache line size: 64-128 bytes

So for example, if using double precision, sizeof(double) = 8 means that 16 double numbers will fit in the same cache line if the cache line size is 128 bytes.

HPP 21 / 47

How do caches work?

- "Direct-mapped cache":
- Hash function maps to a single place for every unique address (multiple sets with a single cache line per set)
- "Set associative cache":
- Cache space is divided into n sets Address is distributed modulo n k-way set associative (k=2...24)
- "Fully associative cache":
- Maps to any slot (single cache set with multiple cache lines)

In practice, k-way set associative commonly used, e.g. L1d cache commonly 2-way set associative.

HPP 22 / 47

How do caches work?

Example

Example: 2-way set associative cache, with 4 sets. Sets A, B, C, D.

Each memory address belongs to one of the 4 sets, this is fixed.

Either of the two "ways" can be used (slot1 or slot2).

Cache: Set A : slot1 slot2

Set B : slot1 slot2
Set C : slot1 slot2
Set D : slot1 slot2

HPP 23 / 47

General caching concepts

- "Cache hit": memory address already in cache good!
- "Cache miss:"
 - Compulsory: On the first access to a block. (also called cold start misses, first reference misses).
 - Capacity: When blocks are being discarded from cache because cache cannot contain all blocks.
 - Conflict: In set associative or direct mapped strategies, conflict
 misses occur when several blocks are mapped to the same set
 or block frame; also called collision misses or interference
 misses.
- "Hit rate" and "miss rate"

HPP 24 / 47

$Cache\ optimization-how?$

Try to increase the chances that the needed memory locations are already in cache:

Nearby memory accesses in time should be to nearby locations in memory

 $\mathrm{HPP} \qquad \qquad 25 \; / \; 47$

Caches and performance

- Caches are extremely important for performance
- Level 1 latency is usually only 1-3 cycles
- Work well for problems with nice locality properties
- Caching can be used in other areas as well, example: web-caching (proxies)
- Modern CPUs have two or three levels of cache
- In the hardware, most of the chip area is used for caches

HPP 26 / 47

Cache optimization example

 $Loop\ order\ for\ matrix-matrix\ multiplication$

```
for (i=0; i<n; i++)
  for (j=0; j< n; j++)
    for (k=0; k< n; k++)
      c[i][j] += a[i][k] * b[k][j];
for (k=0; k< n; k++)
  for (j=0; j<n; j++)
    for (i=0; i<n; i++)
      c[i][j] += a[i][k] * b[k][j];
for (k=0; k< n; k++)
  for (i=0; i<n; i++)
    for (j=0; j<n; j++)
      c[i][j] += a[i][k] * b[k][j];
```

27 / 47

HPP

Test problem, matrices of size 300

CPU used: AMD Opteron 6220 "Bulldozer" @ 3.0 GHz (Tintin cluster at UPPMAX). Compiled using -03.

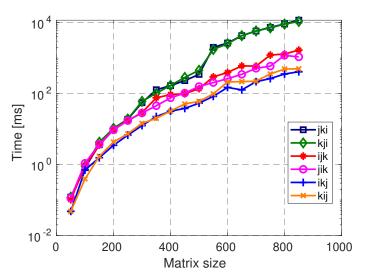

Timings in milli-seconds:

			Loop	o orde	r	
Compiler	ijk	ikj	jik	jki	kij	kji
gcc 4.4.7 (2012)	62	34	64	128	37	128
gcc 4.8.3 (2013)	61	29	63	128	31	128
gcc 5.3.0 (2015)		19	60	128	20	127
gcc 5.3.0 -march=native	65	13	66	128	16	127

Intel icc 16.0.2 (2016)		14	61	131	17	131

Test code mmul_loop_order.c available in Student Portal. Try it!

HPP 28 / 47

Test problem, matrices of size 50:50:850

CPU info: Intel(R) Core(TM) i7-4600U CPU @ 2.10GHz L1d cache: 32K L1i cache: 32K L2 cache: 256K L3

cache: 4096K gcc 8.2.0 HPP 29 / 47

$Cache\ optimizations$

Improve data locality!

Example: blocking

Optimizations can have different effects depending on e.g. prefetching capabilities in the hardware.

HPP 30 / 47

Function side effects are bad

When a function modifies something other than its output value or output arguments, the function has side effects.

Examples: modification of global variables or writing to files.

Function side effects are:

- bad for flexibility
- bad for performance

 $\mathrm{HPP} \qquad \qquad 31 \ / \ 47$

Function side effects are bad

What to do with global variables

When you need global variables Don't use global variables. Avoid it as much as possible.

Ideas:

- Pass as input argument.
- Gather in a structure.

 $\mathrm{HPP} \qquad \qquad 32 \; / \; 47$

More on function side effects

What does the compiler know?

```
int func1(int x) {
  return f(x)+f(x)+f(x);
}
  int func2(int x) {
  return 4 * f(x);
}
```

Are these two equivalent?

Do you know? Does the compiler know?

 $\mathrm{HPP} \qquad \qquad 33 \; / \; 47$

Side effects in loops

What does the compiler know?

```
char str[] = "Hello World!";
int i, sum;
for (i = 0; i < strlen(str); i++)
{
   if (str[i] == '!') str[i] = '?';
   // sum += str[i];
}</pre>
```

What is the complexity?
Can you improve it?
Can the compiler improve it?
Does the compiler know the implementation of strlen(...)?
Check https://godbolt.org/z/cYWoQq

HPP 34 / 47

Pure functions

strlen() is a pure function while rand() is an impure one
Can use gcc __attribute__((pure)) in function declaration to
tell the compiler that a function is pure (free from side effects):

```
int f(int k);

int f(int k) __attribute__((pure));
```

• __attribute__((const)) also exists and is more strict; then the function is not allowed to use pointer arguments. See gcc documentation for details.

HPP 35 / 47

Pure functions

```
int f(int x) __attribute__((pure));
int func1(int x)
{
  return f(x)+f(x)+f(x);
  }
```

Check at https://godbolt.org/z/h3MORO

HPP 36 / 47

Pure functions, example

See text

https://godbolt.org/z/bhYLYw

- Try to specify the function f as pure using __attribute__((const))
- Try instead of doing the __attribute__((const)) declaration, simply move the contents of func.c into main.c.

P 37 / 47

The "const" keyword Letting the compiler know more

Use the "const" keyword to tell the compiler that the value will never change.

Allows compiler to optimize more because the compiler knows more.

Using "const" also helps avoid programming errors, like modifying something by mistake.

 \longrightarrow Using "const" is both good for program design, and good for performance!

HPP 38 / 47

The "const" keyword Example

```
int M = 50;
```

Variable not declared as const \longrightarrow compiler must assume that the value may change.

```
const int M = 50;
```

Variable declared as const \longrightarrow compiler knows value will not change. Compiler may be able to optimize more thanks to this info.

 $\mathrm{HPP} \qquad \qquad 39 \; / \; 47$

Pointer aliasing

Any pointer of unknown origin can reference a value that is accessed through another variable

Any pointer might be used as an array – of unknown size

Multiple "aliases" for the same memory location

Makes compile-time optimization very hard

 \longrightarrow need ways to inform compiler that aliasing does not occur.

 $\mathrm{HPP} \qquad \qquad 40 \; / \; 47$

The "strict aliasing" rule

Default mode in C99 and recent GCC

Pointers of different types are not allowed to refer to the same memory

---- Significant compilation benefits

HPP 41 / 47

The "restrict" keyword

Available in many C/C++ compilers, including recent gcc (sometimes as _restrict)

Within this context, any memory locations accessed by a restricted (pointer) variable will only be accessed through that pointer

Example:

The restrict keyword can have different effect depending on compiler version.

HPP 42 / 47

The "restrict" keyword Example

```
void f(double * v, int N, double* x)
{
  int i;
  for(i = 0; i < N; i++)
    v[i] += ( A + B*x[0] + C*x[1] ) * D;
}</pre>
```

Performance problem due to pointer aliasing?

 $\mathrm{HPP} \qquad \qquad 43 \; / \; 47$

The "restrict" keyword Example

Optimize by adding "restrict" keyword:

No change in function body, only added $_{ ext{HPP}} ext{restrict}$ in argument $_{44\,/\,47}$

The "restrict" keyword Example timings

The restrict keyword can have different effect depending on compiler version.

Code on previous slide, compiled with -03 for different gcc versions:

Compiler	Standard	Optimized			
gcc 4.4.7	1.58	1.19			
gcc 4.8.3	1.07	0.46			
gcc 5.3.0	0.52	0.43			

CPU used: AMD Opteron 6220 "Bulldozer" @ 3.0 GHz (Tintin cluster at UPPMAX).

 $\mathrm{HPP} \qquad \qquad 45 \; / \; 47$

Preparation for the lab on Thursday

We will use valgrind tool: http://valgrind.org/
If you are using your personal computer, check if it exists.

HPP 46 / 47

That's all

Questions?

 $\mathrm{HPP} \qquad \qquad 47 \; / \; 47$
